Topic Outline

- What is a GIS?
- Components of a GIS
- Functions of a GIS
- Data Models used in GIS
- Components of Spatial Data
- GIS Software
- The GIS Process

".....everything that happens, happens somewhere. Knowing '<u>what</u>' is <u>'where</u>' and '<u>why'</u> it is there, can be critically important for decision making. GIS is the technology as well as science to help answer these types of questions and for making intelligent decisions based on space and location.... "

What is a GIS ?

A Geographic Information System (GIS) is an organized collection of computer hardware, software, people, data and workflows designed to efficiently capture, store, query, analyze and display of all forms of spatially referenced data.

Geographic Information Systems (GIS) is a set of tools that integrate and link various components: hardware, software, human capital, data and processes; that capture, store, manage, analyse and model large amounts of geographically referenced information in order to meet the needs related to planning and management

GIS DATA

- A GIS comprises traditional data found on a map and more...
- it utilizes two basic types of data:
- Spatial data:
 - describes the *absolute* or *relative* location of geographic features
- Attribute data:
 - describes the
 characteristics of the
 spatial features
 - Quantitative or qualitative
 - Also referred to as *tabular data (or Aspatial)*

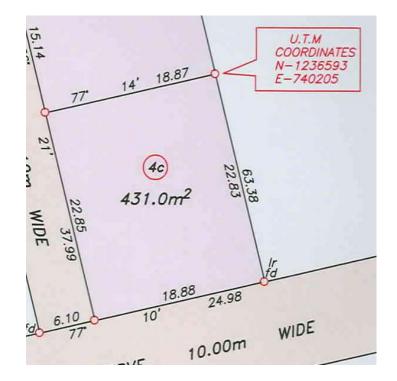

Example

The boundary lines of a parcel would be its spatial data

The characteristics of that parcel: eg. ID, Owner, area, perimeter, address, value, would be attribute data!

Linking Spatial and Attribute Data

Spatial data

- specifies location
- stored in a <u>geodatabase</u> or similar <u>GIS</u> file

Attribute data

- specifies characteristics (what, how much, when)
- stored in a database <u>table</u>

The two are 'Linked' using *relational* database tables

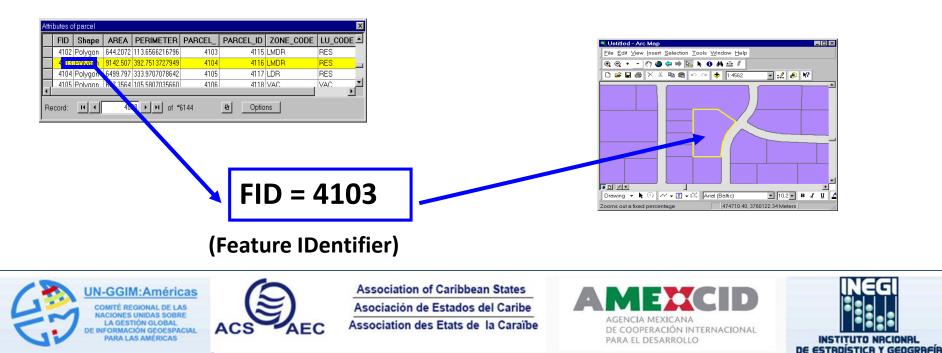

Linking Geometry (spatial) and Attributes

- Geospatial data (features) are stored in tables
- Each feature has a record (row) in the table
 A unique identifier links feature and attributes

Representing Reality: The GIS Data Model

- The real world is broken up into its constituent parts and organized into spatially referenced layers or themes, with each layer representing a common feature.
- A spatial reference system becomes critical for ensuring accurate feature overlaying

The GIS Data Model: Purpose

Allows the **geospatial features** in **real world locations** to be digitally represented and stored in a database so that they can be abstractly presented in **map** form, and can also be worked with and **manipulated** to address some **problem**.

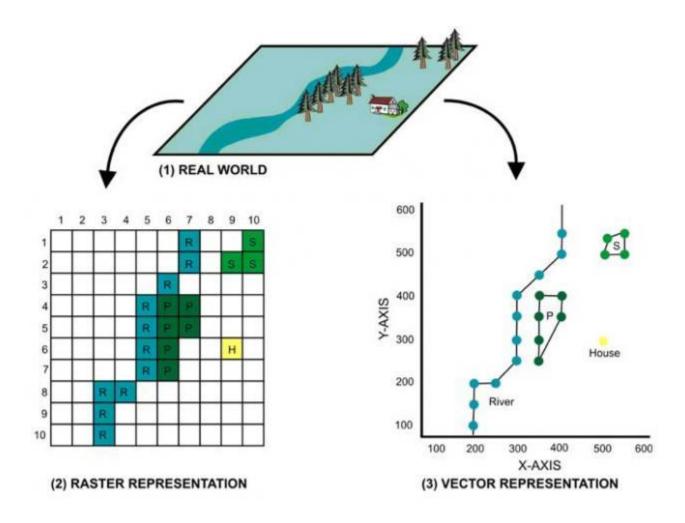

Raster vs. Vector Representation

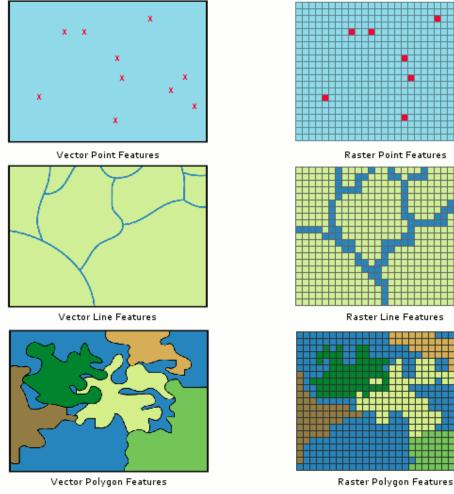

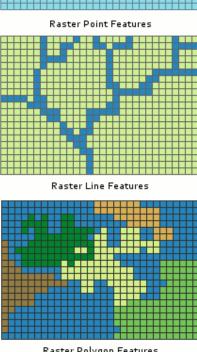

Association of Caribbean States Asociación de Estados del Caribe Association des Etats de la Caraïbe

Raster vs. Vector Representation

UN-GGIM:Américas COMITÉ REGIONAL DE LAS ACIONES UNIDAS SOBRE LA GESTIÓN GLOBAL **NFORMACIÓN GEOESPACIAL** PARA LAS AMÉRICAS

Association of Caribbean States Asociación de Estados del Caribe Association des Etats de la Caraïbe

VECTOR MODEL

- The fundamental concept of <u>vector</u> GIS is that all geospatial features in the real world can be represented either as:
 - Points (nodes): trees, poles, fire plugs, airports, cities
 - lines (arcs): streams, streets, sewers,
 - polygons (areas): land parcels, cities, counties, forest, rock type
- Vector model is best used to represent features with discrete boundaries (roads, buildings, lakes, rivers, administrative boundaries)
- This model tells "<u>where everything occurs</u>", i.e., it gives location to every object.

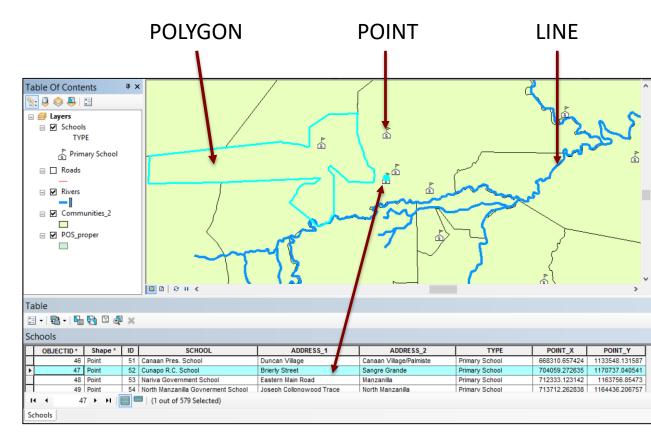

Representing features in vector data

- Real-world entities are abstracted into three geometric shapes:
 - Point
 - Line
 - Polygon
- Each feature type is stored in a separate shapefile or feature class.
- Each feature class contains a table in which each row is a record representing one of the spatial features in the file.

Raster Data Model

- Area is covered by grid with (usually) equal-sized cells;
 - Cells often called pixels (picture elements).
 - Origin is set explicitly.
 - Cell size is always known.
 - Cell references (row/column) are known.
 - Cell values are referenced to row/column location.
- Values represent numerical phenomena or index codes for non-numerical phenomena.

origin	_	x	loca	tion						
۶I	9	4	4	4	0	5	9	9	4	4
y-location	9	5	4	0	6	0	0	7	4	6
⊳	0	7	2	7	8	9	4	7	3	8
,	6	3	1	1	7	8	7	3	6	1
	2	7	6	7	5	7	9	0	7	4
	7	6	2	8	7	8	2	8	5	8
	7	8	7	З	0	9	0	0	5	2
Ţ	5	8	5	5	6	5	3	2	2	1
	6	2	3	4	5	6	9	0	1	4
cell size	6	9	5	1	3	6	6	4	4	1

UN-GGIM:Américas Comité Regional De Las Naciones Unidas sobre La Gestión GLOBAL De InFORMACIÓN GEOESPACIAL PARA LAS AMÉRICAS

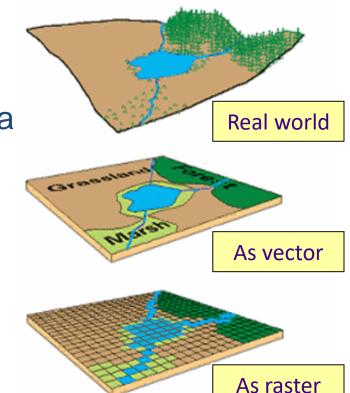

Association of Caribbean States Asociación de Estados del Caribe Association des Etats de la Caraïbe

Raster Data Model

- Advantages of raster over vector
 - Simpler data model
 - Faster processing and display
 - Additional analytic tools
 - Better for unbounded phenomena (like soil pH and elevation)
- Disadvantages of raster
 - Generalization
 - Loss of feature uniqueness

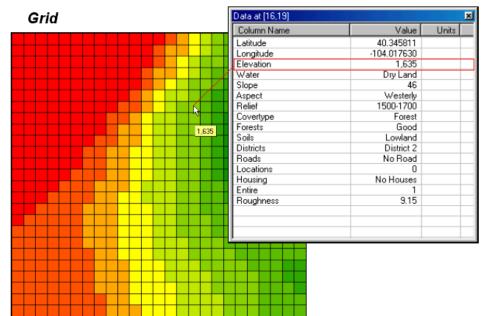

Association of Caribbean States Asociación de Estados del Caribe Association des Etats de la Caraïbe

Raster Data Model

- Attributes are recorded by assigning each cell a single value
- Raster data are good at representing continuous phenomena, e.g.,
 - Wind speed
 - Elevation, slope, aspect
 - Chemical concentration
 - Likelihood of existence of a certain species

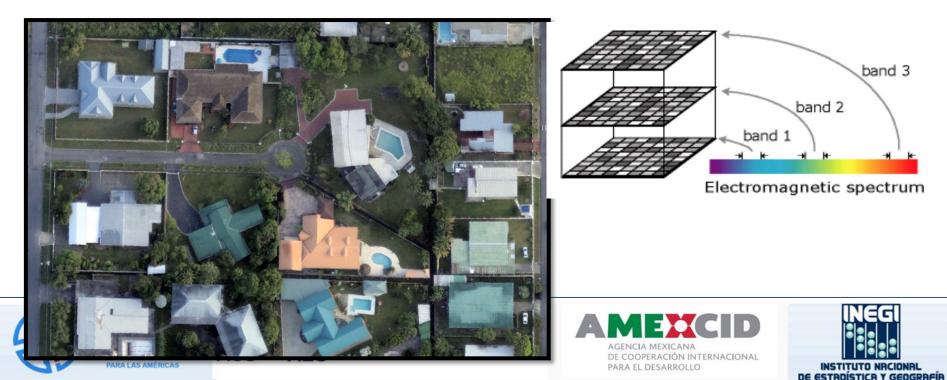

Association of Caribbean States Asociación de Estados del Caribe Association des Etats de la Caraïbe A MEXICANA AGENCIA MEXICANA DE COOPERACIÓN INTERNACIONAL PARA EL DESARROLLO

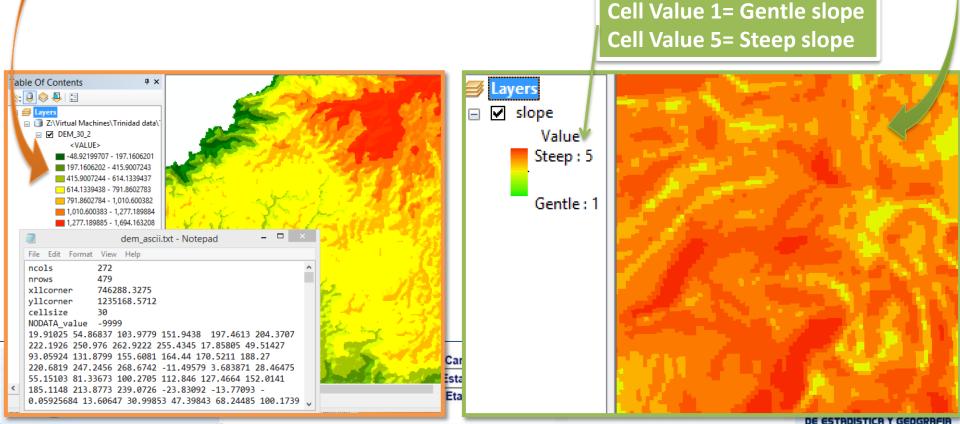

Raster types based on cell values

- In terms of the cell values, rasters can be divided into three types:
 - Image
 - Interpolated and,
 - Thematic
- **Image rasters** have values (Digital Number, DN) that represent measurements of energy (electromagnetic reflections) as captured by a sensor (camera)
- These image raster cell values are usually whole numbers (integers).

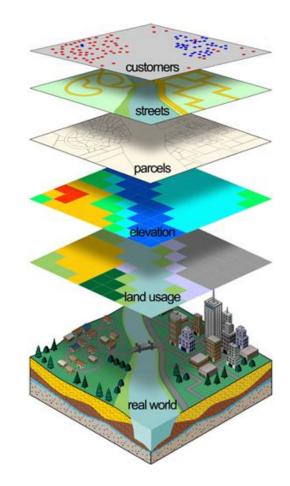

Raster types based on cell values

- Thematic rasters have cell values that represent a particular theme, category/code or class (nominal or ordinal data).
- Cell values in Interpolated rasters usually represent measurements such as elevation, precipitation, soil pH, etc. These values are usually interval or ratio data.

Modelling the Real World

- Objects in the real world are digitally represented then stored in a database.
- Either a vector or raster data model can be used.
- It is common to use both data models to represent different features over a selected project area.

Association of Caribbean States Asociación de Estados del Caribe Association des Etats de la Caraïbe AGENCIA MEXICANA DE COOPERACIÓN INTERNACIONAL PARA EL DESARROLLO

• **Step 1** - Identify possible features from the real world (this example uses the vector data model)

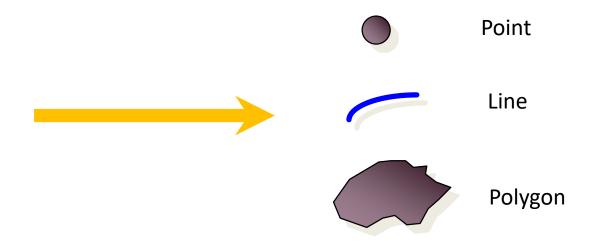

- Buildings
- Road centrelines
- Utility poles
- Water lines
- Manholes
- Road surfaces

 Step 2 - Select a method for representing the feature in the GIS

• Step 3 - Use the selected method to represent the feature in the GIS

Feature : Building Shape: Polygon

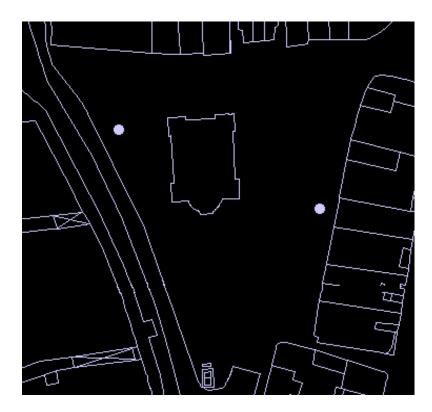

• Step 4 - Identify appropriate attributes for the feature
